## Executive Summary

To better understand the population and demographic factors that will shape the future size and composition of Northern Kentucky's labor force, the Center for Economic Analysis and Development, funded by BE NKY Growth Partnership, projected population and labor force growth for Northern Kentucky and 18 metropolitan statistical areas from 2020 to 2050. The report highlights the intensified national labor competition, with talent shortages impacting site selection decisions. Demographic trends, changing generational preferences, and the rise of remote work contribute to workforce challenges. CEAD analyzed four labor force scenarios to aid policy analysis.

Northern Kentucky consists of Boone, Campbell, and Kenton counties, while CEAD grouped the 18 metros into two categories, close-proximity, and high-growth aspirational. CEAD and BE NKY selected the metropolitan areas in the analysis for two primary reasons. First, Northern Kentucky often competes with the close-proximity (mostly midwestern) metro areas for economic development projects. Second, the high-growth aspirational metros include those that are typically characterized as growth "hot spots" by either the media or industry sources and are similar in size to the metropolitan areas in the close-proximity group. Except for Lexington and Charleston, with populations under 1 million, and Tampa and Detroit, with populations greater than 3 million, the population in the metropolitan areas of interest fall between 1 and 3 million. Table 1 in the report provides a complete list of the 18 metropolitan areas included in the study.

Starting with the 2020 Decennial Census data, CEAD projected population by age and race for each region of interest. CEAD provided four projection scenarios, titled:

- Optimistic
- Aspirational
- Baseline
- Pessimistic

The baseline projection is based on traditional cohort component methodology. This is the "most likely" scenario unless there are either policy interventions or unforeseen economic impacts that change the trajectory of net migration. This projection assumes that local policy will have little, if any, impact on birth and deaths rates.

The pessimistic projection asks what happens to the rate of population growth if the region adopts policies discouraging growth and investment? Or what happens if the region were to lose a major employer or have a major industry shrink substantially? A gradual exit of the auto industry in Detroit would be an example of the latter.

The aspirational projection is the converse of the pessimistic forecast. What happens to the population growth rate if the region emphasizes additional pro-growth policies? What happens if the region substantially invests in its assets, including everything from roads and highways to parks and recreation to education and childcare?

The optimistic projection assumes that in addition to the pro-growth policies and strategies noted under the aspirational projection, these policies start to have a significant impact on the attraction and retention of both employers and employees.

The primary takeaways from the historical trends, current data, and the four population projection scenarios include:

- Broader U.S. population trends are influencing regional outlook. Overall, the U.S. rate of population growth is slowing. At the same time, the population is aging and becoming more diverse. These trends are not playing out evenly across metro areas.
- The current demographics of a region greatly influence its future trajectory.
- Migration is vital to growth, but there is no singular solution to address a slowdown in population growth.
- Similarly, there is no single factor that explains why some metros have experienced growth while others are stable or declining, although there are some shared growth drivers. Notably, the fast-growing aspirational metro regions were not overnight success stories. Most have been experiencing above-average population growth rates for 50 years.
- Baseline projections call for modest population growth in Northern Kentucky and the Cincinnati MSA between 2020 and 2050.
- Baseline projections show the labor force in Northern Kentucky growing modestly while the labor force in the overall Cincinnati MSA will contract between 2020 to 2050.

Northern Kentucky is not an island unto itself. While Northern Kentucky's population growth is expected to outpace that of the Cincinnati MSA, the region is tied to the economic and demographic prospects of the larger metro area. Further, given its unique geographic positioning, Northern Kentucky's growth trajectory will be influenced by policy makers in both Frankfort and Columbus.

## Rate of population growth is slowing

Historical trends highlight three key points. First, population growth rates peaked between 1990 and 2000, corresponding roughly to the Millennials' birth years. Second, the rate of population growth varies significantly across U.S. regions. Third, across most metropolitan areas, the population is aging.

Between 1970 and 2020, the U.S. population grew by 62.7 percent, adding 127.7 million people. The annual growth rate increased from 1.1 percent (1970-1980) to 1.3 percent (1990-2000) but slowed to 0.7 percent in the last decade (2010-2020).

Between 1970 and 2020, Northern Kentucky's population grew by 58.8 percent, adding 147,559 people while Cincinnati's population increased by 32.8 percent, adding 557,281 people.

Population growth between 1970 and 2020 varied across 384 U.S. metro areas, with larger metros generally growing faster. ${ }^{1}$ Among 18 metros of interest, Northern Kentucky, if classified, would be among smaller metros. Its 58.8 percent growth from 1970 to 2020 places it in the third quintile among smaller metros with a 2020 population of less than 500,000 .

[^0]
## Population is aging

The population projections through the next quarter-century show that the U.S. population will continue to age. By 2050, in the Cincinnati MSA 22.4 percent of the population will be 65 years and over, up from 16 percent in 2020. In Northern Kentucky 24.4 percent of the population will be 65 years and over in 2050, up from 15.1 percent in 2020.

The aging of the population is reflected in both the Old Age Dependency Rate and the Youth Dependency Rate. Each rate reflects the number of dependents per 1,000 people of working age. In Northern Kentucky, under the baseline population projection, the old age dependency ratio will increase from 23.2 in 2020 to 41.5 in 2050, an increase of 18.3. The Cincinnati MSA old-age dependency ratio will rise from 24.7 in 2020 to 37.1 in 2050, an increase of 12.4. Under the baseline population projection, the youth dependency ratio fell between 2020 and 2050 in both Northern Kentucky and the Cincinnati MSA.

## Population is becoming more diverse

Racial and ethnic diversity is emphasized for its role in economic growth, contributing to innovation, workforce utilization, entrepreneurship, and meeting diversity, equity, and inclusion goals. Population projections for the four scenarios include data for White, Black, Hispanic, and All Other groups. The White population is projected to decrease as a percentage of the total, becoming less than half of the U.S. population by 2050.

Northern Kentucky faces a challenge in its relative lack of racial and ethnic diversity. Although it is projected to become more diverse, with the White population falling from 84.8 percent in 2020 to 78.1 percent in 2050 , it will still be less diverse than any of the 18 metros of interest.

The Cincinnati MSA is projected to become more diverse as well, with the White population falling from 75.9 percent in 2020 to 67.1 percent in 2050.

In the United States, the Hispanic population is among the fastest growing racial groups. Hispanic women in recent years have had among the highest birth rates relative to other racial/ethnic groups. It is notable that among the close-proximity metropolitan areas, each has a relatively small Hispanic population accounting for 10.5 percent or less of total population. In Northern Kentucky the Hispanic population is just 4.5 percent of total population. Among the high-growth aspirational metros, the Hispanic population generally accounts for a higher percentage of the total population topping out at 31.9 percent in Austin.

## A region's current demographics influences its future trajectory

Three main factors determine a region's population growth: births, deaths, and net migration. All else equal, if a region is relatively young it will have a higher birth rate than a region with an older population. Likewise, in general, the White population has a lower fertility rate than the Black and Hispanic populations. And of course, an older population will typically have a higher death rate. Without significant changes in net migration rates, a region's future population is largely determined by its current demographics. The baseline projection assumes that the current demographic baseline and trends in a region will continue going forward. Without a significant change in migration rates, it is unlikely that a region will move from its baseline forecast.

Migration is vital to growth, but there is no singular solution to address a slowdown in population growth

In general, high-growth aspirational metros experience faster growth due to domestic net migration. In contrast, Cincinnati, Northern Kentucky, and many close-proximity metros rely more on natural change and international net migration. In-migration means new talent, which has the potential to drive innovation, household formation, elevated birth rates and new business creation, among other things.

Domestic net migration has averaged 433 people annually since 2010 in Northern Kentucky, contrasting with the Cincinnati MSA loss of 1,803 people annually.

Assuming a consistent natural change rate (births minus deaths), achieving the optimistic projection from the baseline projection in the Cincinnati MSA would require attracting 12,502 people annually. Similarly, Northern Kentucky would need to attract 2,402 people annually to reach the optimistic forecast from the baseline while holding natural change constant. In other words, the region would need to increase net migration from its historical average of 433 per year to 2,402 per year, an increase of 1,969 , an annual increase of more than 400 percent.

The starting age profile, economic conditions, and amenities influence population growth. Younger populations tend to grow faster, and economic factors and amenities play roles in attraction and retention. No single factor explains growth patterns across metros; for example, Nashville's rapid growth contrasts with Memphis's relative stagnation despite each having a similar climate and state tax environment. Yet, some common characteristics of growing metros include the presence of state government (i.e. a state capital), major research universities or other large postsecondary institutions, strong offerings in entertainment and amenities as well as a relatively low cost of living.

## Fast-growing aspirational metro regions were not overnight success stories

One of the striking differences between the close-proximity and high-growth aspirational metropolitan regions is the large differences in population growth, both historically and projected through 2050.

Only three of the close-proximity metropolitan areas exceeded the U.S. average rate of growth in population including Indianapolis (up 64.2 percent), Columbus (up 78 percent), and Lexington (up 93.3 percent). On the other hand, all of the high-growth aspirational metros have experienced population growth at more than double the U.S. average, ranging from a low of 138.5 percent in Charleston to a high of 472.1 percent in Austin. In other words, the high-growth aspirational metros are not overnight success stories. They have been outpacing U.S. population growth for the past 50 years.

Baseline projections show modest population growth in Northern Kentucky and the Cincinnati MSA from 2020 to 2050.

Projections suggest a slowing growth rate of population growth for Northern Kentucky and the Cincinnati MSA, with modest growth under each scenario except for the pessimistic.

- The pessimistic scenario anticipates population declines, with an average annual decrease of 0.1 percent in Northern Kentucky and an average annual decline of 0.4 percent in the Cincinnati MSA between 2020 and 2050.
- The baseline scenario predicts modest population increases, with an average annual increase of 0.5 percent in Northern Kentucky and an average annual increase of 0.1 percent in the Cincinnati MSA during the same 30 -year period.
- The aspirational scenario predicts faster population growth with an average annual increase of 0.6 percent in Northern Kentucky and an average annual increase of 0.2 percent in the Cincinnati MSA during the same 30-year period.
- The optimistic scenario predicts the fastest population growth with an average annual increase of 1.1 percent in Northern Kentucky and an average annual increase of 0.7 percent in the Cincinnati MSA during the same 30-year period.

Baseline projections show the labor force in Northern Kentucky grows modestly and the labor force in the Cincinnati MSA will decline from 2020 to 2050.

CEAD estimated the workforce size by determining the prime working-age population (15 to 64 years) and applying region-specific, age-specific labor force participation rates (LFPR). The assumption is made that LFPR rates will remain constant from 2020 to 2050. Both Cincinnati and Northern Kentucky show normal distributions of LFPR, with the highest participation rates among individuals aged 20-59 and lower participation rates for persons under 20 years of age and those 60 years and over. Today, the region benefits from a relatively high participation rate, so efforts to drive workforce expansion through increased participation will be difficult.

For the Cincinnati MSA, the baseline projection anticipates a decline of 31,685 in the labor force by 2050, with only the optimistic scenario predicting an increase (100,261). Northern Kentucky's baseline projection forecasts a slight increase of 8,450 in the labor force, while the pessimistic scenario predicts a decline of $\mathbf{1 7 , 9 5 0}$.

Notably, the aspirational forecast shows a smaller increase in the labor force compared to the baseline forecast, which is attributed to differences in age distribution. The age distribution influences LFPR, and regions with a younger population tend to have higher LFPR. The correlation between population growth and labor force growth is emphasized, with high-growth aspirational metros experiencing a positive relationship due to an increase in working-age population driven by domestic net migration.

## Conclusion: High, Low, and Stagnant Population Growth Tradeoffs

There are tradeoffs associated with high, low, and stagnant population growth rates. There is no singular optimal rate of population growth that is right for every community, rather stakeholders must decide on growth policies that reflect community goals and values.

As previously discussed, benefits of population growth include increased income, jobs, innovation, consumer demand, and an expanded tax base. However, downsides encompass resource scarcity, environmental degradation, infrastructure strain, housing shortages, and pressure on the educational system. As exemplified by Austin, rapid growth may lead to housing shortages, increased homelessness and rapid rise in the cost of living.

Population decline also poses challenges, as reduced demand may discourage new housing construction. Housing preferences may shift to suburbs, causing inner-city vacancies, as seen in Detroit, where a response to population decline has been mass demolition of vacant housing.

Population stagnation correlates with limited economic growth and an aging population as younger residents seek opportunity elsewhere, increasing old-age dependency ratios, and straining social services. Pittsburgh, Cleveland, St. Louis, and Detroit face challenges due to the lack of robust growth.

An aging population brings economic challenges, including increased healthcare costs and pressure on social security. Slow labor force growth or shrinkage may increase dependency ratios, posing long-term fiscal challenges for governments.

The rate of population growth significantly influences a region's labor force growth and composition. A shrinking population coupled with falling labor force participation rates may limit a region's economic growth.

Potential solutions for labor shortages include increased immigration and job automation. Immigration, a key aspect of U.S. labor force policy, depends on regional factors. Automation, effective in maintaining economic efficiency with a shrinking labor force, may eliminate less skilled jobs. If both immigration and automation fail, there is a risk of declining innovation and economic productivity.

## Introduction

The Center for Economic Analysis and Development (CEAD), with funding from BE NKY Growth Partnership, forecasted population growth for Northern Kentucky and 18 metropolitan statistical areas by race and age for the 30 years 2020 to 2050. CEAD then developed a forecast for each area's available workforce based on these population and age component projections during the same 30 -year period.

Over the past decade, and exacerbated by the Pandemic, the competition for labor has heated up across the country. Talent and labor availability challenges have a significant impact on site selection decisions. In the most recent Site Selectors Survey, " 75 percent of respondents said they were having a significant effect; 25 percent said they were having some effect; and no one said they were having zero effect. ${ }^{י 2}$ Numerous factors affect the U.S. labor market. Chief among these factors are demographic trends, fueling shifts in the size and composition of the labor force. Preferences are changing, driving settlement patterns, with many Americans preferring to live in warmer climates to the south and the west and to lower-cost metropolitan regions. To stay competitive, many employers have embraced remote, hybrid, and other flexible scheduling options to attract and retain talent.

With talent in short supply and key to attracting and retaining employers, the ability to predict labor force growth and implement successful workforce strategies have become paramount concerns for regional economic development organizations. BE NKY asked CEAD to analyze the current labor force and provide projections for the population and the labor force under four scenarios. The baseline projection provides CEAD's best estimate of future population and workforce levels. The pessimistic, aspirational, and optimistic scenarios provide alternative predictions, allowing for policy analysis assuming different inputs and outcomes.

Throughout this report, CEAD defined Northern Kentucky as Boone, Campbell, and Kenton counties. Additionally, BE NKY identified 18 metropolitan statistical areas (MSA) as regions of interest. ${ }^{3}$ CEAD divided these 18 metro areas into two groups. The first group, close-proximity Metros, includes 11 metropolitan statistical areas: Cincinnati, Cleveland, Columbus, Indianapolis, Kansas City, Lexington, Louisville, Memphis, Nashville, Pittsburgh, and St. Louis. The second group, high-growth aspirational metros, includes seven metropolitan statistical areas: Austin, Charleston, Charlotte, Denver, Nashville, Raleigh, and Tampa. CEAD and BE NKY selected the metropolitan areas in the analysis for two primary reasons. First, Northern Kentucky often competes with the close-proximity metro areas for economic development projects. Second, the high-growth aspirational metros are often highlighted by the media and in industry rankings for having above-average population growth. At the same, they are similar in size to the metropolitan areas in the close-proximity group. Except for Lexington and Charleston, with populations under 1 million, and Tampa and Detroit, with populations greater than 3 million, the other metropolitan areas in the analysis had a 2020 population between 1 and 3 million people.

[^1]

|  | St. Louis, MO-IL |

## Section I: Historical Population Trends 1970 to 2020

Between 1970 and 2020, the U.S. population grew by 62.7 percent, adding 127.7 million people. Across the decades, U.S. population growth rose from an average annual rate of 1.1 percent between 1970 and 1980 to a yearly average of 1.3 percent between 1990 and 2000. Since 2010, the average annual population growth rate has slowed to 0.7 percent in the last decade ending in 2020 (Fig. 1).

During this same 50 -year period, the population in the Cincinnati MSA grew by 32.8 percent, adding 557,281 people. From 2010 to 2020, the population in the Cincinnati MSA grew, on average, 0.5 percent yearly, adding 116,118 people (Fig. 2).

Simultaneously, between 1970 and 2020, the population in Northern Kentucky grew by 58.8 percent, adding 147,559 people. From 2010 to 2020, the population in Northern Kentucky grew, on average, 0.8 percent per year, narrowly outpacing the rate of U.S. population growth, which averaged 0.7 percent yearly (Fig. 3).

Population growth rates varied substantially across the 18 metros included in our analysis. Over the 50 years, while the U.S. population increased by 62.7 percent, the population of Pittsburgh fell by 14.2 percent, a decline of 391,450 people. During the same period, the population of Austin increased by 472.1 percent, adding nearly 1.9 million people. Neither Northern Kentucky nor the Cincinnati MSA matched the growth of the overall U.S. If Northern Kentucky were its own MSA, its population growth of 58.8 percent would rank 11 out of 19 (Fig. 4).

Population growth varied substantially across the 384 MSAs in the United States. CEAD compared growth rates for metro areas with a 2020 population of less than 500,000 , metro areas with a 2020 population between 500,000 and 1 million, and metro areas with a 2020 population of 1 million or more.

In general, larger metropolitan areas grew faster than smaller metro areas. However, each size category had an extensive range in growth rates. Among our 18 metro areas of interest, 16 had a population of 1 million or more. Two metros of interest, Lexington and Charleston, had populations between 500,000 and 1 million. Comparing the Northern Kentucky population change from 1970 through 2020 of 58.8 percent against metro areas with less than 500,000 people would place the region in the third quintile of growth among these smaller population metro areas (Fig. $5,6,7$ ).

Among the close-proximity metros, cumulative growth between 1970 and 2020 ranged from a loss of more than 391,000 in Pittsburgh to a gain of 917,525 in Columbus. Only three of the closeproximity metros, Indianapolis, Columbus, and Lexington, grew as fast as the United States during the 50 years 1970-2020 (Fig. 8).

Across the high-growth aspirational metros, cumulative growth between 1970 and 2020 ranged from a gain of 466,292 in Charleston to more than 2 million in Tampa. The high-growth aspirational metros grew much faster than the United States during this period (Fig. 9).

The historical data show two key points to understanding future growth patterns. First, most regions' rate of population growth peaked sometime between 1990 and 2000. The ten years between 1990 and 2000 closely correspond to the end of the birth years for Millennials born
between 1981 and 1996. Second, the population growth rate varies substantially across regions in the United States.

Appendix A provides historical population data and trends across the 18 metro areas of interest from 1970 through 2050.

## Section 2: Components of Population Change 201D to 2022

There are three main components of population change: births, deaths, and migration. Across the country, fertility rates have been declining for most groups for decades, with variations in rates by race and age. Mortality rates, excluding the COVID-19 pandemic years, have been declining for most groups, again varying by age, race, and gender. However, migration rates differ substantially across the country. ${ }^{4}$ Changing a community's migration rate via public policy efforts is the primary way to change a region's population trajectory.

So, what is driving the faster growth in our high-growth aspirational metros compared to our closeproximity metros? It is the rate of domestic net migration. Austin, Charleston, and Charlotte, for example, each have 60 percent or more of their overall change in population coming from domestic net migration.

Conversely, growth in the close-proximity metros depends more on international migration and natural increase (births minus deaths). Only three metros, Cleveland, Tampa, and Pittsburgh, had cumulative natural decreases in population between 2010 and 2022. All 18 metro areas of interest along with Northern Kentucky had cumulative increases in international net migration during the period. Six of the 18 metro areas had cumulative declines in domestic net migration, led by Detroit, with losses of more than 242,000. Tampa and Austin had domestic net migration of 434,969 and 423,939, respectively.
Cincinnati and Northern Kentucky have relatively low domestic net migration, with most of their population change coming from natural growth. Making your region attractive for domestic migration is a crucial strategy for population growth (Fig. 10, 11, 12).
Northern Kentucky's domestic net migration has averaged 433 people per year since 2010. For the Cincinnati MSA, domestic net migration averaged a loss of 1,803 people per year since 2010. During this same period, domestic net migration for Tampa averaged 33,459 people per year, accounting for 77.5 percent of its total population growth since 2010. In Charleston, domestic net migration averaged 9,552 people annually, accounting for 68.8 percent of its population growth since 2010. Conversely, in Detroit, domestic net migration has accounted for a loss of 18,637 people per year, on average, since 2010.

International migration can also affect a region's overall population growth. While Detroit, Cleveland, and St. Louis saw a significant exodus via domestic net migration, all three metros had positive international net migration. Since 2010, international net migration added 129,626 people to Detroit, 46,423 to Cleveland, and 45,230 to St. Louis metro areas. In the Cincinnati MSA, international net migration has totaled 45,264 since 2010 , averaging nearly 3,500 people annually. In Northern Kentucky, international net migration has added almost 5,100 people since 2010, averaging 389 people annually (Fig. 13, 14).

Many communities experienced declines in natural growth during the pandemic years. Among our metros of interest, for example, Charleston, Charlotte, Cincinnati, and Denver, among others,

[^3]had declines in natural growth in 2021 and 2022. Tampa and Pittsburgh saw the largest net declines in natural growth during the pandemic.

Another not-so-obvious variation that leads to different rates of population growth is a region's starting age profile. All else being equal, the younger a region's population is, the faster it is likely to grow since young adults have higher fertility rates. Likewise, all else being equal, the older a region's population, the slower it will grow since an aging population has fewer children and higher mortality rates. Across the 18 metros in the analysis and Northern Kentucky, the median age in 2022 ranged from a low of 35.9 years in Austin to a high of 42.9 years in Pittsburgh. The U.S. median age is 39 years. It's 38.3 in the Cincinnati MSA. Median age in Northern Kentucky ranges from a low of 37.7 in Boone County to a high of 39.8 in Campbell, with Kenton falling in between the two at 38 years (Fig 15). Seemingly minor differences in median age can significantly impact the natural rate of population increase. Across all metropolitan areas in the United States, the median age ranges from 25.7 years in Provo, Utah, to 68.6 years in The Villages, Florida.

Demographics are not the only factor impacting the rate of population change across regions. Other factors include a region's economic conditions, such as having high/low poverty rates, high/low incomes, high/low rates of job growth, and the educational attainment levels of the population. A region's amenities, such as being a state capital, having a robust educational system, or having natural amenities such as mountains, all play a part in population attraction and retention.

It is a popular narrative that the only regions enjoying robust population growth are those in warm climates. While warm weather is undoubtedly a factor in migration patterns, it does not explain the rapid growth of regions such as Denver.

In particular, Nashville's rapid population growth has garnered national attention. From 1970 through 2020, the population of Nashville increased by more than 1.2 million, growing, on average, 3.1 percent annually. During this same period, Memphis added 423,000 people, growing, on average, just 0.9 percent annually. Despite similar weather, Nashville's population growth rate is three times that of Memphis. While warm weather is undoubtedly helpful in attracting people, weather alone is not enough.

Appendix B provides data on the components of population change from 2010 through 2022 for the 18 metros of interest and Northern Kentucky.

## Section 3: Papulation Projections 2020-2050

Given the lack of available county-level population projections, CEAD utilized an analysis from the Columbia University Center for International Earth Science Information Network. ${ }^{5}$ The Columbia University projections provide data for every county in the United States, allowing CEAD to aggregate county-level data for each metro area of interest in the analysis. Further, these data included projections for each 5 -year age cohort from 0 to 4 years through 85 years and over, which allowed CEAD to aggregate relevant age groups to estimate the size of a region's labor force over time. Also included are projections for population across four race and ethnic groups: White, Black, Hispanic, and Other. ${ }^{6}$ CEAD benchmarked these projections to the 2020 Decennial Census. The projections included different scenarios. CEAD used four of those scenarios, titled:

- Optimistic
- Aspirational
- Baseline
- Pessimistic

To test our methodology, CEAD compared our Northern Kentucky baseline forecast for 2050 to that of the Kentucky State Data. ${ }^{7}$ Over a 30-year forecast horizon, the difference in estimates for 2050 was fewer than 3,000 people or $0.64 \%$. The Kentucky State Data uses cohort component methodology to forecast population similar to that of the U.S. Census Bureau. According to the State Data Center, the cohort component model "captures the impact of the primary components of population change - births, deaths, and net migration - to forecast changes in future population."

As noted by the author, Hauer,
"These projections, like all projections, involve the use of assumptions about future events that may or may not occur. Users of these projections should be aware that although the projections have been prepared with the use of standard methodologies, documentation of their creation, open-source computer code, and extensive evaluations of their accuracy and uncertainty, they might not accurately project the future population of a state, county, age, sex, or race group. The projections are based on historical trends and current estimates. Any small error in the projections early in the projection horizon could cascade into considerable errors decades later in the projection. Caveat emptor users beware. These projections should be used only with full awareness of the inherent limitations of population projections in general."

[^5]Each of the four scenarios examines how a region's demographics, economics, and policies might change over the projection horizon from 2020 through 2050.

The baseline projection is based on traditional cohort component methodology. The baseline projection is expected to be the most likely scenario unless policy interventions change the trajectory of net migration. This projection assumes that local policy will have little, if any, impact on birth and death rates.

The pessimistic projection asks what happens to the rate of population growth if the region adopts policies discouraging growth and investment. Or what happens if the region loses a major employer or has a major industry shrink substantially? The contraction of the auto industry in Detroit provides an example of how a pessimistic scenario might play out over time. Additionally, a region may not adapt to structural changes in the economy such as the transition from the internal combustion engine to electric vehicles, leading to job loss.

The aspirational projection is the converse of the pessimistic forecast. What happens to the rate of population growth if the region were to implement pro-growth policies? What happens if the region makes substantial investments in its assets, including everything from roads and highways to parks and recreation to education and childcare? An example of a potential policy change would be higher density residential zoning allowing for a more rapid expansion of affordable housing.

The optimistic projection assumes that in addition to the pro-growth policies and strategies noted under the aspirational projection, these policies start to have a significant impact on the attraction and retention of both employers and employees.

Each of the four scenarios has a different path to population growth or decline. They are not simply linear differences in projected growth rates. For example, if a region implements policies and makes investments to attract younger people to the region, that is likely to accelerate a region's growth rate. Younger people tend to have more children, all else equal. However, it is also possible to implement policies that attract and retain an older population. In this case, all else equal, an area attracting and retaining an older population may experience faster population growth, but nevertheless, have a small response to the size of its workforce. Like age, the diversity of a region's population impacts its rate of population growth via differences in birth and death rates.

The projections generally show a slowing rate of growth for Northern Kentucky and the Cincinnati MSA. Except for the pessimistic projection, the forecasts suggest modest population growth. Consistent across the four scenarios, the population in Northern Kentucky is projected to grow faster than in the Cincinnati MSA (Table 4, 5).

Sharp readers will notice that the 2020 population estimates shown in Section 1, Historical Population Trends, and the 2020 population estimates in this section do not match. The historical population estimates are the Census Bureau's mid-year population estimates as of July 1, 2020. The projections start with the 2020 Decennial Census population as of April 1, 2020. The difference between the two sets of numbers is slight. The difference for Cincinnati is 783 people or 0.035 percent. The difference for Northern Kentucky is 564 people or 0.141 percent.

## Pessimistic Projection

The pessimistic projections anticipates population declines in Northern Kentucky and the Cincinnati MSA. The projection estimates a decrease of 10,641 for Northern Kentucky and a decline of 272,705 for the Cincinnati MSA. In this scenario, Northern Kentucky exhibits an average annual population decrease of 0.1 percent, while the Cincinnati MSA experiences an average yearly decline of 0.4 percent during the 30 years.

## Baseline Projection

The baseline projections predict modest population increases. The projection estimates a population increase of 58,429 in Northern Kentucky and an increase of 86,653 for the Cincinnati MSA. In this scenario, Northern Kentucky is projected to see an average yearly population increase of 0.5 percent, and the Cincinnati MSA will see an average annual population increase of 0.1 percent over the next 30 years.

## Aspirational Projection

The aspirational projections forecast population increases in Northern Kentucky and the Cincinnati MSA. The projection estimates a population increase of 69,020 in Northern Kentucky and an increase of 133,534 for the Cincinnati MSA. Under this scenario, Northern Kentucky is projected to experience an average yearly population increase of 0.6 percent, and the Cincinnati MSA is projected to experience an average annual population increase of 0.2 percent over 30 years.

As noted above, projections scenarios are not simply linear differences. The population of Northern Kentucky is 2.3 percent higher under the aspirational forecast compared to the baseline projection. The projected labor force in 2050 for Northern Kentucky is smaller under the aspirational forecast than under the baseline forecast. This is due to changes in the overall age structure. In the baseline projection in 2050 there are 111,344 people ages 65 and over compared to 125,428 people in this age group under the aspirational forecast, an increase of 12.6 percent. This has implications in the calculation of future labor force size in Section 7. All else equal, persons over the age of 65 have a lower labor force participation rate.

## Optimistic Projection

The optimistic projections forecast population increases in Northern Kentucky and the Cincinnati MSA. The projection estimates a population increase of 130,480 in Northern Kentucky and an increase of 461,725 for the Cincinnati MSA. Under this scenario, Northern Kentucky is projected to experience an average yearly population increase of 1.1 percent, and the Cincinnati MSA is projected to experience an average annual population increase of 0.7 percent over 30 years.

Appendix C presents data tables showing the population projections from 2020 through 2050 for the other metros of interest for each of the four scenarios.

## Section 4: Migration Acrass Projection Scenarios

The rate of domestic and international migration varies substantially across the 18 metros of interest. The close-proximity metros have relatively low levels of domestic net migration compared to the high-growth aspirational metros. As was illustrated in Section 2, Fig. 13, and Fig. 14, since 2010, domestic net migration in the Cincinnati MSA has been negative (down 1,803 on average annually) and slightly positive in Northern Kentucky (up 433 on average annually).

Assuming a constant rate of natural change, the Cincinnati MSA would need to attract 12,502 people annually to achieve the optimistic projection from the baseline projection. For Northern Kentucky to reach the optimistic projection from the baseline projection holding natural change constant, the region must attract 2,402 people annually.

## Figure 16: Average Annual Net Migration Needed to Reach Dptimistic Papulation Projection from Baseline

## Section 5: Changes in Population Age 2020-2050

Median age, as shown in Section 2, Figure 15, provides a snapshot of a region's age in comparison to other areas; yet "there is more to the age structure of the population than the snapshot that median age alone can provide." ${ }^{8}$

Two valuable measures are the Youth and Old Age Dependency Ratios. The Youth Dependency Ratio is the ratio of individuals under 15 years per 100 people of working age 15 to 64 years. The Old Age Dependency Ratio is the ratio of individuals 65 years and over per 100 people of working age 15 to 64 years of age. In 2020, Northern Kentucky and the Cincinnati MSA had relatively high Youth Dependency ratios among the 18 metros of interest, at 30.6 and 29.5, respectively. Memphis had the highest Youth Dependency ratio at 31 compared to Pittsburgh's low of 24.2 (Fig. 17).

The Old Age Dependency ratio ranged from a low of 17 in Austin to a high of 34.2 in Pittsburgh across the 18 metros of interest. Old Age Dependency ratio in the Cincinnati MSA was 24.7 and 23.2 in Northern Kentucky - the middle of the pack (Fig. 18).

As noted earlier, the demographics of a community today have an outsize impact on the future demographics of a region. That is evident across the five projections. Age distributions vary significantly by projection scenario, accounting for different birth, death, and migration rates across the MSAs.

Across the four projection scenarios, the population is predicted to age leading to an increase in the old-age dependency ratio for all 18 metros of interest and Northern Kentucky (Fig. 19). In Northern Kentucky, under the baseline projection, the old age dependency ratio will increase from 23.2 in 2020 to 41.5 in 2050, an increase of 18.3. The Cincinnati MSA old-age dependency ratio will rise from 24.7 in 2020 to 37.1 in 2050, an increase of 12.4 . The baseline forecasts Lexington to have the lowest old-age dependency ratio in 2050 at 32.2 , with Tampa having the highest at 46.6. The region experiencing the most significant increase in its old age dependency ratio is Raleigh, up 22.3 from 19 in 2020 to 41.3 in 2050.

Under the baseline projection, the youth dependency ratio fell in Northern Kentucky and the Cincinnati MSA. Eight of the metros of interest are projected to have an increase in their youth dependency ratio. In contrast, the other ten metros of interest are forecasted to have decreases in their ratios. In 2050, Memphis will continue to have the highest youth dependency ratio at 31.6, while Pittsburgh will have the lowest at 23.7 (Fig. 20).

While the youth and old age dependency ratios are important, they do not describe the population change that is working age.

In 2020, the percentage of the population in the Cincinnati MSA aged 15 to 64 years accounted for 64.8 percent of the population. By 2050, under the baseline projection, the percentage of the population in the prime working age will fall to 60.3 percent (Fig. 21). In Northern Kentucky, the percentage of the prime-age population will fall from 65 percent in 2020 to 58.8 percent in 2050 (Fig. 22).

[^6]Appendix D provides baseline projections data by age for Northern Kentucky and the 18 metros of interest.

## Section G: Changes in Population Diversity by Race and Hispanic Drigin 2020-2050

Just as the population of the United States will age over the 30 -year projection horizon, it will also become more racially diverse. How do you define racial diversity? The Census Bureau's concept of racial and ethnic diversity refers to "the representation and the relative size of different racial and ethnic groups within a population. Diversity is maximized when all groups are represented in an area and have equal shares of the population." ${ }^{9}$

The diversity index is one method for measuring diversity. The index estimates the probability that two people chosen at random will be from different race and ethnic groups. The diversity index can range from 0 to 1 . A zero value indicates that everyone in the population has the same racial and ethnic characteristics, while a value close to 100 indicates that everyone in the population has different characteristics. A diversity index of 61 means that there is a 61 percent chance that two people chosen at random were from different racial or ethnic groups. ${ }^{10}$

In 2020, among the 18 metros of interest the diversity index was the lowest for Pittsburgh (31.5), followed by Cincinnati at 40.5 . The highest diversity index was in Austin (64.1), followed by Memphis (61.5). Northern Kentucky's Diversity Index was just 27.5 (Fig. 23).

Racial and ethnic diversity can play a significant role in economic growth by:

- Promoting innovation and creativity
- Increasing the utilization of a region's talent/workforce
- Fueling entrepreneurship and small business growth
- Ensuring firms can meet their diversity, equity, and inclusion (DEI) and Environmental, Social, and Governance (ESG) goals

The population projections for the four scenarios provide data on four race and ethnic groups including White, Black, Hispanic, and All Other. Except for the Charleston MSA, across the 18 metros of interest, the White population is projected to shrink between 2020 and 2050 as a percentage of the total population. While the Cincinnati MSA and Northern Kentucky will become more diverse, they will remain less diverse than many of the metros of interest.

Nationally, less than half the U.S. population is projected to be White by 2050. Across the 18 metros of interest, Memphis will have the smallest White population at 30.5 percent compared to Pittsburgh's 74 percent. A challenge for Northern Kentucky is its relative lack of racial and ethnic diversity. Northern Kentucky will become more diverse between 2020 and 2050, with the White population falling from 84.8 percent in 2020 to 82.6 percent in 2050 . However, the region will remain less diverse than any of the 18 metros of interest (Fig. 24).

Appendix E provides baseline population projections by race and ethnic origin for Northern Kentucky and the 18 metros of interest.

Figure 24: Baseline Projections Change in Percent of Total Population 2020-2050

## Section 7: Labor Force Projections 2020-2050

Several demographic factors impact the size of a region's labor force, including:

- overall size of the population
- age distribution of the population
- the ethnic and racial diversity of the population, and
- the labor force participation rate of individual demographic groups

Other non-demographic factors often impact a region's labor force participation rate including educational attainment levels, retirement trends, economic conditions, government policies, technology changes, and cultural and social factors.

Demographic and non-demographic factors often work together. For example, immigration can boost a region's labor force by bringing in new workers. A region's overall quality of life, including healthcare, housing, and recreational opportunities, can help attract immigrants.

To estimate the size of the workforce of each region of interest, CEAD first determined the population within prime working ages, 16 to 64 years of age. This calculation determined the maximum potential workforce, assuming everyone in the age group opted to participate in the labor force. CEAD then applied region-specific, age-specific labor force participation rates (LFPR) to the prime working-age population. In the absence of forecasts of labor force participation rates from 2020 through 2050, CEAD made the simplifying assumption that age-specific LFPR rates would remain constant through the forecast period.

Cincinnati and Northern Kentucky both generally follow a normal distribution of labor force participation rates that would be expected, with individuals aged 20-59 having the highest labor force participation rates and the younger and older groups having lower rates (Fig. 25).

The baseline projection for the Cincinnati MSA is forecasting a decline of 31,685 in the labor force between 2020 and 2050. Of the four forecast scenarios, only the optimistic projection predicts an increase in Cincinnati's labor force $(100,261)$.

The baseline projection for Northern Kentucky is forecasting a slight increase of 8,450 in the labor force between 2020 and 2050. Only the pessimistic forecast predicts a decline in the region's labor force of 17,950 (Tables 8, 9).

One striking feature of the labor force predictions is that the increase in the labor force is forecasted to be less under the aspirational forecast than under the baseline forecast. The age distribution of the population varies across the four projection scenarios. The baseline projection has a larger labor force than the aspirational projection. This difference is due to the baseline projections, which have a smaller but younger population, which all else being equal, have higher labor force participation rates. A region's labor force is as much a function of its age distribution as its population. For example, Memphis has the lowest LFPR among the 18 metros of interest, given that the region has a relatively large share of its population under 16 years of age. On the other hand, Tampa has the second lowest LFPR, given the large share of its population over the age of 65 years.

In general, across the high-growth MSAs, labor force growth is predicted for each of the four scenarios. While the high-growth metros are experiencing the same phenomenon of rapid aging, their overall population growth, mainly driven by domestic net migration, is enough to result in a net increase in their working-age population and, thus, their workforce.

There is a strong correlation between population growth and labor force growth. While events such as the Pandemic and the Great Recession can create periods of increasing population growth with a decline in employment, the relationship between population and labor force growth is positive over the long run.

Among the Proximity Metros, given the relatively modest population projections, the forecasts for labor force growth are modest, and in some cases, negative.

While the analysis assumed constant LFPR, there is further risk if these rates continue to decline over time. Potential levers that could help overcome this limited growth in labor force are explored in section 8 .

Appendix F provides labor force projections across each of the four scenarios for the 18 metros of interest and Northern Kentucky.

## Section 8: High, Low, and Stagnant Papulation Srowth Tradeoffs

Just as there is no universally agreed-upon threshold for what rate of inflation is considered "too high," as it can depend on various factors, including economic conditions, policy objectives, and public expectations, there is no universally agreed-upon threshold for the optimal rate of population growth in a region. Central banks and policymakers often target a specific inflation rate that they believe is consistent with their goals for economic stability and growth. Likewise, a community needs to target a rate of population growth that it believes is consistent with its goals for the community.

At the regional level, there are costs and benefits to population growth, status quo, and decline.
The benefits of population growth are easy to enumerate: increases in income, jobs, innovation and entrepreneurship, consumer demand for goods and services, and an increased tax base. There are downsides to population growth as well. These include resource scarcity, environmental degradation, infrastructure strain, housing shortages, and pressure on the educational system. An unfortunate outcome of rapid population growth is often housing shortages, which in turn can lead to higher levels of homelessness. Among our metros of interest, Austin has experienced a rapid increase in homelessness as a result of housing scarcity and higher prices.

Population decline comes with challenges as well. If a region's population declines, there is little reason to build new housing. However, as housing preferences change, current residents may move further out to suburbs, where new housing developments offer a wider array of housing options. Population decline often leads to large numbers of vacant homes in the inner city with little resale value. The poster child for this phenomenon is the city of Detroit. The large-scale demolition of houses in Detroit began in the early 2000s and gained momentum over the years in response to population declines within the city.

Population stagnation, or status quo, is not without challenges. Chief among the challenges is limited economic growth. Additionally, declining or stagnant growth often correlates with an aging population, resulting in a higher old-age dependency ratio, which strains a region's social services and healthcare systems. The relatively high old-age dependency ratios in Pittsburgh, Cleveland, St. Louis, and Detroit are due in no small part to a lack of robust population growth. A lack of population growth can limit the expansion of the tax base, which may lead to fiscal challenges for local governments in funding public services, especially the repair and replacement of vital infrastructure.

An aging population presents several economic challenges for a region. Increased healthcare costs and the pressure on social security are often discussed. Additionally, slow labor force growth or shrinkage can increase dependency ratios in some areas. As a result, governments may face longterm fiscal challenges as they grapple with the need to fund pensions, healthcare, and social services for an aging population. Population stagnation or decline coupled with an aging population could lead to difficult decisions about taxation, public spending, and the overall structure of social welfare programs. For example, how does a region prioritize spending on services for younger people, such as public education, versus providing services for an aging population, such as senior services?

The rate of a region's population growth has significant implications for a region's labor force growth and composition. A shrinking population coupled with falling labor force participation rates will likely limit a region's ability to grow its economy or maintain its current economic status.

What are potential solutions for labor shortages? Two often discussed solutions are increased immigration and the automation of jobs.

Immigration has long been at the heart of U.S. labor force policy. Many policies have been used to increase or decrease the immigrant population in the U.S. over the years. At the regional level, whether a region attracts domestic or international immigrants depends on numerous factors.

Automation is another option when a region faces the possibility of a stagnant or shrinking labor force. If the manufacturing industry can automate a certain percentage of open jobs, then even with a shrinking labor force, there would be a better chance that economic efficiency would be maintained. Automation could also benefit the labor force by eliminating dangerous or undesirable jobs. Suppose automation is not effective in filling positions that are left open, and immigration does not fill available jobs; in that case, there is a risk that innovation and economic productivity will decline.

## Conclusion

The analysis of historical population trends, components of population change, and population projections for the period 1970 to 2050 provides valuable insights into the demographic dynamics of the Cincinnati Metropolitan Statistical Area, Northern Kentucky, and the other 17 comparison metros.

Over the past 50 years, the U.S. experienced significant population growth, with the rate of growth peaking between 1990 and 2000. The Cincinnati MSA and Northern Kentucky followed similar trends, although their growth rates did not match the overall U.S. growth.

The examination of components of population change, from 2010 to 2022 highlights the critical role of migration, both domestic and international, in shaping population trends. High Growth metros like Austin, Charleston, and Charlotte attribute a substantial portion of their population change to domestic net migration, while close-proximity metros, including Cincinnati and Northern Kentucky, rely more on international net migration and natural increase.

The population projections for 2020 to 2050 reveal four distinct scenarios-Optimistic, Aspirational, Baseline, and Pessimistic - each based on Shared Socioeconomic Pathways. These scenarios anticipate varying rates of growth or decline for Northern Kentucky and the Cincinnati MSA. Notably, the Pessimistic Projection foresees population declines, emphasizing the importance of understanding potential challenges and planning for mitigating factors.

The analysis extends to the changing age structure of the population, with projections indicating an aging population across all scenarios. The Youth and Old Age Dependency Ratios shed light on the demographic challenges and opportunities, emphasizing the importance of understanding age-related dynamics in population change.

Racial and ethnic diversity emerges as a crucial aspect, with Diversity Index measures revealing the relative homogeneity of Northern Kentucky compared to other metros. Despite projections showing increased diversity, the region lags behind in overall diversity, posing challenges for economic growth.

Labor force projections further illuminate the intricate relationship between demographic factors and economic considerations. Cincinnati and Northern Kentucky exhibit unique labor force dynamics, influenced by age distribution, racial distribution, and migration patterns, across the various projection scenarios.

In summary, this analysis underscores the complexity of population dynamics in the Cincinnati MSA, Northern Kentucky, and other metros. While historical trends provide context, the future trajectory is subject to various factors, making it imperative for policymakers, planners, and community leaders to consider these findings in shaping strategies for sustainable growth, addressing challenges, and fostering inclusive development.

[^0]:    ${ }^{1}$ Metropolitan areas are defined (geographically delineated) by the Office of Management and Budget (OMB) bulletin no. 20-01 issued March 6, 2020.

[^1]:    ${ }^{2}$ Site Selectors Survey, Site Selection magazine, January 2023
    ${ }^{3}$ Per the U.S. Census Bureau, "the general concept of a metropolitan area is that of a core area containing a large population nucleus, together with adjacent communities that have a high degree of economic and social integration with that core." In other words, an MSA includes a large central city with a population of at least 50,000 and its surrounding suburban counties.

[^2]:    Data source: U.S. Bureau of Economic Analysis, Table CAINC4

[^3]:    ${ }^{4}$ Per the Census Bureau, "The estimates of net international migration include all foreign-born immigrants and emigrants, regardless of legal status. Thus, unauthorized migrants are implicitly included in Census Bureau estimates of net international migration, although it is not possible to tabulate separate estimates of unauthorized migrants."
